

The review API accepts both GET and POST requests. When a post request is received, it should place the topic, category, general rating out of 5, and then all the specific ratings for the category selected into the database. Since there are multiple other special ratings that don't apply to the category, the API just defaults those values to 0. For the GET request, the API receives the topic and category, and returns all the reviews for it along with only the *relevant* information for it. For example, if housing is chosen, it will return the community rating out of 5, but not taste rating since that doesn't apply to the category.
